ABSTRACT: Valves for hydro power projects are installed for safety, maintenance, and shut-off, as well as for flow and pressure regulation. A Butterfly valve is a type of flow control device, which is widely used to regulate a fluid flowing through a section of pipe. This type of valve is mainly used as safety valve, turbine inlet valve, and pump valve for low to medium design pressures. They are operated by oil hydraulic systems for opening and closing or by closing weight and hydraulic pressure for opening. For turbine inlet valves, oil pressure can also be taken from the governor hydraulic oil system. The sealing system is of flexible, adjustable rubber/metal type to reduce leakage to a minimum. Water flow through the valve is possible in both directions. The main objective of this thesis work is to analyses the option of fabricated variant for door & body in place of casted, reduction in the material of valve body & door by structural design & FEM analysis & optimization in the material of valve component. The 3D modelling to be performed for butterfly valve by using CAD software. Further the stress & displacement FEM analysis of the butterfly valve to be performed by using ANSYS tool to evaluate the optimized result.

KEYWORDS: Butterfly valves, body, door, FEM analysis, hydro power, Structural.

I. INTRODUCTION

Hydro power is considered as one of the most economical and non-polluting sources of energy. Power generation from the water is termed as Hydroelectricity. Hydroelectricity means electricity generated by hydro power or from the use of the gravitational force of falling water or flowing water. One of the most common forms of power generation since this form of energy neither produces direct waste matter nor it is subjected to exhaustion.

Now a day’s more and more hydro electrical power plants being setup and renovated. But still the design and development of hydro electrical power plant is based on the traditional methods. Therefore there is a huge scope of utilization of modern day’s technique like finite element method (FEM) for achieving maximum possible optimization. In any power plant valves for different purposes are usually needed. Normally it is a shut-off valve just in front of the turbine. In this way the turbine may be emptied without emptying the shaft or penstock. In addition the guide vane cascade is depressurised so that leakage flow is avoided.

Butterfly valve detail: These specialized Butterfly valves are installed to protect hydro-electric installations against the possibility of penstock rupture. Valves are designed to close against turbine runaway during an emergency condition. These valves act as isolating devices for inspection of penstock without dewatering entire head race tunnel. Yet another important application is for large water supply schemes fed from reservoirs through long pipelines, failure of which can cause disastrous floods. Valves by virtue of their design and robust construction, close down automatically and instantaneously in the event of the downstream pipeline failure. These valves close during over velocity condition occurring due to turbine trip or runaway condition.
Butterfly valves are normally applied in front of low and medium head water turbines, i.e. heads up to 200 m. For high head power plants the butterfly valve is from time to time used as a closing device in inlet tunnels and alternatively as emergency closure valves.

## II. RELATED WORK

However, only studying the fluid characteristics is not enough for the large diameter butterfly valve because the pressure produced by the fluid is too high, which has great effect on the stress distribution in valve. Valves are very widely used for hydro mechanical part which is used to control the flow of water under high heads.

The butterfly valve is one of the types of shut-off devices most commonly employed in hydropower station and systems. Its use is favored because of their relatively low cost, compactness, light weight, reasonable water tightness and simplicity of operation.

This dissertation describes the design optimization of butterfly valves using CAD software and ANSYS. To structural design the butterfly valve for weight optimization the vonmises stress & maximum deformation value are found out by using ANSYS and compare stresses value for existing casted verses optimized fabricated design for door and body of butterfly valve.

Analysis of the butterfly valve is done to optimize the stresses and minimize the weight using ANSYS. The mathematical model of optimization is established firstly, and the FEA is carried out by using the ANSYS software. Based on the analysis of optimal result, the stress concentrates on the valve has become evaluate, which provides a better reference for redesign of valve.

## III. BASIC DESIGN CRITERIA FOR BUTTERFLY VALVE COMPONENT

For design of valve components (valve disc, valve body & valve trunnion) reference consideration are taken from the IS 7326 (Part 1): 1992 deals with the structural and hydraulic aspects of design, formulas are taken from various design books (e.g. Roark’s formulas for stress & strain, design data book etc.) & various reference from other existing designs.

The main characteristics of this butterfly valve are: nominal diameter $D=2000$ mm, nominal pressure $P_n=1.128$ MPa, hydraulic test pressure $P_h=1.962$ MPa.

**Valve Body Design consideration**

- The body may be made in a single piece or in parts for convenience of manufacture, transport to site and erection.
In case of butterfly valves used as a turbine inlet valve, the body should be designed to avoid abrupt changes in velocity. The shell of the body should be designed such as to sustain maximum static head including pressure rise. Supporting feet for installing the valve on its foundation should be provided.

- The body should have two hubs for trunnion bearing housings.
- The fasteners should be of corrosion resistant steel; otherwise they should have corrosion resistant coating.

**Valve Disc Design consideration**

- The design of all types of discs should be such as to offer minimum head loss in the open position and to sustain the full differential pressure across the closed valve.
- The disc may be split in parts for ease of manufacture, transport and erection. Disc should be stress relieved before taking up for machining operation.
- The angular travel of disc should be nearly 90° from open to shut-off position.
- Thrust collar should be provided to hold the disc in the center of valve body.

IV. **MODEL GEOMETRY DESCRIPTION**

3D modelling is carried out with the help of CAD software UGNX-8 by using the existing design details. A separate model is prepared for the analysis of casted & fabricated valve disc & body.

V. **MESHING OF BUTTERFLY VALVE**

Meshing is carried out with ANSYS software, a tetrahedral element were used for meshing the model with prism layer for modelling boundary layer with smooth transition as shown in next slide. After meshing we obtained 10898 nodal points and 5625 coarse elements for Disc & 19270 nodal points and 10420 coarse elements for Body.

A. Fixed support at valve body pedestal
B. Loads: At normal pressure on the inner cylindrical surface $P_n=1.9621$ Mpa, the load on the body

### VII. **FINITE ELEMENT ANALYSIS RESULT**

FEA result for valve disc: As a result of finite element analysis, were obtained the von Mises equivalent stress & total deformation shown in figure for disc casted & disc fabricated variant of the butterfly valve. The major parts of equivalent stresses do not exceed $\sigma=225$ N/mm$^2$, which are smaller than admissible stress value $\sigma_a=1.5\times150=225$ N/mm$^2$. The maximum total deformation value for disc in closed position is $0.3426$ mm (casted) & $0.8499$ mm (fabricated) at centre of the disc.

![Figure 10: von Mises equivalent stress for valve disc casted](image10)

![Figure 11: Detail showing the area of maximum von Mises equivalent stress for Butterfly valve disc casted](image11)
FEA result for valve body: As a result of finite element analysis of equivalent stress (von Mises) at working pressure of 1.962 N/mm² are within the allowable stress range for the most required areas for both the situation in which the disc is in the open position and the situation in which the disc is in the closed position. Also we obtained the maximum values for the equivalent stresses in these areas.

As from the summary of the result:

- We find that, the Von Mises Stress induced in the parts of Butterfly Valve because of applied pressure of 1.962 N/mm², are less than the yield strength of the material.
- Hence we conclude that, Design of Butterfly Valve for chosen material is safe.
We compared the initial design with the optimal design. It is found that the weight reduction up to 39% is possible in the modified design compared to the initial design.

Static analysis of finite element of butterfly valve disc & body allows quantitative and qualitative assessment of the state of stress and strain by highlighting critical areas:

Valve disc - equivalent stress appear in the transition area between support rib and disc seat area.

Valve body – equivalent stress appear in the surface contact between trunnions disc and hub body.

Von Mises equivalent stresses do not exceed $= 225 \text{ N/mm}^2$; than admissible stress value $\sigma_a = 1.5 \times 150 = 225 \text{ N/mm}^2$. Accordance to maximum deformations is produced on the top and bottom of the valve body & valve disc and does not exceed 1.3 mm.

The maximum value of von Mises equivalent stress of 162.3 MPa is obtained at a single point on valve disc and is due to boundary conditions.
