ABSTRACT: The key objective of this paper is to monitor the data and control the data regularly. By using a technology like PC Based Wireless process the real time data acquisition wirelessly using Supervisory Control and Data Acquisition. In large industries several processes are carried on regularly, so there is a necessity to observe all the processes and govern the factors affecting the process for that we can use this paper. In that different sensors i.e Humidity, moisture, Temperature, Rainfall sensors are interfaced to the AT89S52 microcontroller. Information collected from the sensors is continuously sent over 2.4GHz trans-receiver wirelessly to the microcontroller which is then received at the corresponding 2.4 GHz USB type trans-receiver connected to a PC / Laptop. We can customize parameters like set point, lower limit and higher limit on the SCADA screen. As the different sensor goes below set point the microcontroller issues command to the respective relay. Higher limit and lower limit features are present for producing an alarm on the PC in the event of breakdown of system. Therefore, processes at dangerous places can be controlled with good accuracy by using wireless device to monitor the parameters so that we can take certain steps even in worst case. Few years back the use of wireless device was very less, but due to the rapid development in technology now a days we use maximum of our data transfer through wireless like Wi-fi, Bluetooth, Wi max, etc.

KEYWORDS: PC, Microcontroller, Zigbee module, Data acquisition, SCADA, Microcontroller, Trans-receiver, Sensors.

1. INTRODUCTION

The main use of this module helps in an industry during the worst cases as the analog device may be damaged may be during the fire accidents, etc. But with the wireless transmission we not have an accurate data but when compared to the analog failure the errors are very minimum so we use wireless to monitor the parameter in an industry where their no means of human interface to monitor the parameters In this paper we deal to monitor the parameter through wireless by using zigbee ready platform which is based on the IEEE 802.15.4, 2.4 GHz, in this module we use msp 430 for the voltage and other technical parameters, which has in build RAM in it. The working of this module is simple in principle, the changes in certain place is monitor in real time process which is very accurate in monitoring and their no other interface and other disturbance in monitoring the parameter in this project we monitor temperature and humidity with the help of respective sensors. The change in the room temperature, humidity can be monitored like real time as the change is displayed in respective interval in the visual basic screen.

A PC Based Supervisory Control and Data Acquisition (SCADA) system is a usually a distributed computerized system used to control and monitor the field devices from a centralized location. Field devices include temperature, humidity, rainfall, pumps, heaters, alarms, control valves etc.

The objectives of this SCADA system are as follows:
1. To Monitor the system.
2. To control the system
3. To Reduce the staff through automation or by operating a system from a single central location.
4. To Store the data of system.
In today’s world most of the large scale industries have become automated. Industries require monitoring and controlling as they do large amount of production. This project concentrates on making automation efficient and economical so that even small scale and medium scale industries get benefited. Our proposed SCADA system is divided into three sub systems Master Terminal Unit (MTU), Remote Terminal Unit (RTU) and Communication network. The MTU is usually a computer, RTU consists of Microcontroller, Sensors, ADC and other IC and communication is through ZIGBEE technology.

II. RELATED WORK

This new technique was first implemented by Siddique M with his colleague [1-7]. will describe design work, involved in development of a PC based Supervisory Control, Data Acquisition system for Real Time Monitoring and Control of Industrial Parameters in order to provide an efficient automated environment in industries, where the process is geographically scattered and the centralized control is required. A certain model has been developed containing controller based Data Acquisition Card which act as Remote Station. The information gathered in Remote Station from sensors/detectors is fed to Master Terminal Unit. The Master Terminal Unit (MTU) is a general purpose PC equipped with monitoring capabilities and has the ability to remotely issue controlling commands by the virtue of Graphical User Interface. The information can be shared on wired or wireless network. This application specific and cost effective model of circulatory fluidized bed combustor will provide efficient and cost effective model of control system. ZIGBEE is a wireless technology and is interfaced with microcontroller in many applications like home automation. ZIGBEE with microcontroller is also used for temperature control where we have used the two modules among them one is at the RTU, which includes the controller AT89S52 and that is interfaced with temperature sensor and ZIGBEE module. Second module is at the MTU connected to the PC/Laptop. The module at RTU continuously checks the status of the sensors attached with that and sends the current status via ZIGBEE to the module at MTU then the MTU compares the status with data stored and take the action according to the predefined program.

III. ARCHITECTURE

Architecture contains the pair of ZIGBEE modules, Microcontroller (AT89S52), ADC0808, LM35 Temperature, Humidity, rainfall sensors, Relay driver (ULN2003), and SCADA software installed in computer. At the computer process control and monitoring takes place. Sensors, ZIGBEE and other inputs are connected at the RTU and the RTU is connected to the MTU wirelessly via ZIGBEE trans-receiver. output of the other side PC connected with ZIGBEE directly through the USB port and this ZIGBEE will communicate with RTU through another ZIGBEE as shown in fig 1 and display the status in SCADA.

Fig. 1 Architecture of the system

As shown in fig 1 ZIGBEE is directly connected to USB port of PC/Laptop and on the other side microcontroller is interfaced with ZIGBEE module at the Remote Terminal unit. When inputs are active, will send the status to RTU
and after processing the status RTU will send the data to PC via ZIGBEE and that will be displayed on SCADA software. Now user will respond to that status by passing the command to RTU to process the output.

**BLOCK DIAGRAM:**

**CIRCUIT DIAGRAM:**

![Circuit Diagram](image)

In that Fig.3 The sensors are used for the weather parameters are LM35 for the temperature sensing, HIH3160 series is used and a short circuit is used for the rain fall sensing is used. The data form this is transmitted through the ADC conversion circuit where the analog data from the parameter transducers are changed to digital form.
by the circuit used. There are different sensors which are connected with ADC and ADC is connected with the microcontroller which is seen on the LCD and the PC.

MICROCONTROLLER:

The AT89S52 is a low-power, high-performance CMOS 8-bit microcontroller. The in-system programmable Flash memory is 8K byte. Atmel’s high-density non-volatile memory technology is used to manufacture this microcontroller and is compatible with the industry-standard 80C51 instruction set and pin-out. Using conventional non-volatile memory programmer or on-chip Flash the program memory can be reprogrammed. Atmel AT89S52 is a powerful microcontroller which provides a highly-flexible and cost-effective solution to many embedded control applications as it combines a versatile 8 bit CPU with in-system programmable Flash on a monolithic chip.

The specifications of AT89S52 are a flash memory of 8K bytes, RAM of 256 bytes, 32 input and output lines (I/O lines), watchdog timer, two data pointers, three 16 bit counters, an architecture of six - vector two level interrupt, a duplex serial port, on-chip oscillator and on board circuitry clock. For further insights in AT89S52, it is designed with operation down to zero frequency by static logic and has two different power saving modes. It also has an idle mode, which stops the CPU which enables the RAM, serial port, counters and interrupt system to function. The power down mode conserve the RAM contents by freezing the oscillator and disabling chip functions until the hardware reset or next interrupt.

In this paper microcontroller is interfaced to ADC0808, ZIGBEE module, and relay driver. The analog to digital convertor converts the analog data collected from the temperature sensors into digital format and gives it to the microcontroller. The ZIGBEE module in the RTU sends this data from microcontroller to MTU. The information obtained from the MTU is again given to microcontroller and then to the relay driver to drive the output.

ZIGBEE Module:

ZIGBEE is a device that is based on IEEE 802.15.4 standard as shown in fig 4. ZIGBEE is into the class of wireless domain like GSM and RF technology. As it is wireless, the maintenance of the wires and the cost will be effectively reduced compared to the other wired technologies. ZIGBEE also provides a certain bit ON/OFF level to the receiver side so that the same data is transmitted from the transmitter as the wired technologies provide. Thus ZIGBEE replaces the connecting wires and provides a wireless communication.

![Fig. 4 ZIGBEE module](image)

ZIGBEE has four layers based on ISO model. They are physical layer, media access control layer, network layer and application layer as shown in fig 4. It contains three nodes and they are sink node, routing node, terminating node. Sink node is initialized first and during this network and equipment parameters are configured. After configuration it selects the channel for connection to the network. It is fully controllable node. Routing node can be join or re-join the network and also scans channel for new connection. It will act like sink node after the regular operation. Terminal nodes in normal operation just sends or receive data and as a super node it will select the nearest sink or transceiver.
IV. VISUAL BASIC FOR SCADA

VISUAL BASIC is used to develop SCADA software. On start-up, Visual Basic 6.0 will display the following dialog box as shown in figure 6. One can choose to start a new project, open an existing project or select a list of recently opened programs. A project is a group of files that makes an application. Various types of applications we can be created, however, we will concentrate on creating Standard EXE programs (EXE means executable program). Click on the Standard EXE icon to enter the VB programming environment.

Fig 5: Basic model of Zigbee

Fig. 6 Visual Basic Start-up Dialog Box
As shown in Table 1, the weather has been observed in °C on the LCD display in winter and summer season respectively. In Winter season the climate condition is cold therefore the measured temperature is found 23°C to 25°C. During summer season the climate condition is hot therefore the measured temperature is found 39°C to 41°C.

2) RELATIVE HUMIDITY

As shown in Table 2, the relative humidity has been observed in % on the LCD display. A 12 hour analysis is made from 9 AM to 9 PM. It is noted that Relative humidity found to be higher side during morning and evening time. On the other hand it seems to be low during afternoon time.
SOFTWARE RESULTS

The software results are obtained from visual basic. In that the temperature range is set from 10 °C to 40 °C. If the temperature is within that range then software output shows green signal.

VI. CONCLUSION

Data acquisition and data logging is the most important aspect of any measurement system. Data acquisition uses data acquisition hardware and a computing device to acquire real time data from the field and display it in monitor. Data acquisition can be PC based wireless. In PC based data acquisition, the PC is used where in wireless data acquisition transmitter and receiver is used to acquire the data. This project develops a hardware prototype of PC based and wireless based data acquisition system for a greenhouse applications. Different physical parameters like temperature, Humidity, Rainfall, Light intensity are acquired and logged. Wireless data acquisition system is developed to monitor temperature in wireless domain.

This project can be used in industries as well as domestic applications wherever automation is needed. Further this project can be upgraded using advanced technologies, to control the voltage, current and other factors like speed, intensity etc., of the desired machines.
