ABSTRACT: In coastal areas most of the land is covered by soft Clay. The construction of a structure on the soft Clay is quite miserable due to its inadequate engineering properties. Improvement of subgrade using conventional design methods which are preloading, dredging, and soil displacement techniques, among all these methods, the Stone column technique is preferred because it provides the primary aspect of reinforcement and also to improve the strength and reduces the settlement when Stone column loaded in soft Clay undergoes excessive bulging due to inadequate lateral support from the surrounding Clay soil. To avoid excessive bulging, Stone column is encased with geo grids. In present study experiments done on Stone column with and without encasement. The floating Stone column is reinforced with geo-grids of varying encasement depths of 0.25L, 0.5L, 0.75L, L to improve bearing capacity and reduce lateral bulging.

KEYWORDS: Stone column, Geo-grid, Encasement, Soft Clay, Bulging

I. INTRODUCTION

Areas particularly coastal region are covered with the thick layers of Soft Clay soil deposits having very low shear strength and high compressibility. These Soft Clay soil deposits are not suitable for the formation of sub-grade. Due to excessive settlements, large lateral flow of soft Clay underlying structures results in loss of global and local stability. In view of the increasing developments in the coastal region in the recent past industries, a number of ports, buildings, roads, tunnels, bridges are being built. Construction of highway embankments using conventional design methods which are preloading, dredging, and soil displacement techniques, among all these methods, the Stone column technique is preferred because it provides the primary aspect of reinforcement and also to improve the strength and reduces the deformation. Another major advantage of this technique is the simplicity of its construction. The load carrying capacity of the Stone column is a function of the rate of application of the load and the lateral confinement offered by the surrounding soil. In very soft soils this confinement is very low and consequently, failure occurs. The use of compacted Stone columns as a technique of soil reinforcement is frequently implemented in soft cohesive soils to increase the bearing capacity of the foundation soil, to reduce the settlement, and to accelerate the consolidation of the surrounding saturated soft soil.

When the Stone columns are installed in very soft Clay deposits, the surrounding Clay cannot provide adequate support to the Stone column to withstand loads resulting in excessive bulging, so the performance of Stone columns can be improved by providing weak deposits with reinforcement and reducing column bulge effectively. Alternatively, the Stone columns are reinforced internally by stabilization of column material using concrete plugs, chemical grouting or by adding internal inclusions (geo-grids, geo-textiles, plastic fibers etc.). In the present study, the encasement of Stone column with geo grids at different reinforcement depths is performed in the laboratory through strain controlled load test. The effect of the parameters such as, the depth of geo-grid reinforcement from bottom level, and its lateral bulging at different depths was analysed.
II. MATERIALS USED

Materials introduction
The materials that are adopted in this study are soft Clay, stone aggregate, Geo-grids, Sand. The sources and properties of these materials described in below.

Soft Clay
Soft Clay is excavated from Visakhapatnam port trust at coast guard where piling work is being carried out. The soil is highly compressible Clay.

![Fig.1 Soft Clay sample](image1)

Stone aggregate
Pure granite crushedstone aggregateis used as a backfill in this study. These aggregates are collected from madhava crushers in anakapalli and aggregates retained on 10mm and passing through 12.5mm are taken for the present study. The physical properties of stone aggregates are given below.

3.4 Sand
The sand is collected from government provided ramps in srikakulam. The sand adopted is classified as well graded.

III. EXPERIMENTAL PROGRAM

Experimental program carried out includes the construction and testing procedures of Clay bed, ordinary floating Stone column and reinforced Stone columns.

Preparation of Clay bed
The air-dried and pulverized Clay sample was mixed with required quantity of water to achieve uniform consistency. Moisture content of 35% is added to the soil. Initially soil is thoroughly mixed with water to get uniform consistency. The container walls are coated with grease to decrease adhesion between the walls of the container and the Clay bed. The uniformly mixed paste was then filled in the tank in layers of 50mm thickness to the desired depth of 300mm by means of hand compaction to get desired dry density. For each load test, the Clay bed was prepared afresh in the test tank and Stone columns were installed in it. After preparation of Clay bed, it is covered with wet gunny cloth and then left for 24 hours for moisture equalization. Figure 5 shows the Clay bed prepared in the cylindrical tank used in this study. Tests were conducted on Stone columns formed in a Clay bed of 200mm diameter and 300mm height. Figure 6 shows the Schematic view of Stone column foundation for test.
**Construction of ordinary floating Stone column**

As shown in fig 7 the Clay bed was prepared to a desired depth of 100mm, the centre of the cylindrical mould was properly marked and the pvc pipe of 50mm diameter was placed at the the marked portion of mould. Around this pipe, Clay bed was prepared in three layers each of 50mm for compaction till the entire Stone column is formed. In this studystone aggregates was used as the backfill. Add 2.6% of water to the coarse aggregate to avoid the absorption of water from surrounding Clay bed. The Stone column material charged into pvc pipe to certain level, compacted withdrawal of pipe were carried out simultaneously. After compaction of each layer, the pipe is lifted gently to a height such that there will be an overlap of 5mm between the surface of the stone chips and the bottom of the casing pipe. The aggregates were compacted by 10mm diameter tampering rod with 10 blows from a height of fall of 100 mm. Further the bed prepared should left for 24 hrs covered with polythene cover to ensure proper contact between the Clay and Stone column and to gain strength of disturbed Clay.
Construction of laterally confined Stone columns with geogrids:
After the Clay bed was prepared to a desired depth of 100mm, the centre of the cylindrical mould was properly marked and the PVC pipe of 50mm diameter was placed at the marked portion of mould. Around this pipe, Clay bed was prepared in three layers each of 50mm for compaction till the entire Stone column is formed. The reinforced Stone column portion is provided after ensuring proper reinforcement depth from bottom. Here geogrid material is used as an encasement to reinforce the Stone column. After ensuring reinforcement depth the geo grid shell as shown in the figure 8 is placed in the PVC pipe. The Stone column material charged into PVC pipe to desired level of reinforcement (0.25L, 0.5L, 0.75L and L from bottom) compacted withdrawal of pipe were carried out simultaneously leaving the geo grid shell with stone aggregates. After compaction of each layer, the pipe is lifted gently to a height such that there will be an overlap of 5mm between the surface of the stone chips and the bottom of the casing pipe. The aggregates were compacted by 10mm diameter tampering rod with 10 blows from a height of fall of 100 mm. Further the bed prepared should left for 24 hrs covered with polythene cover to ensure proper contact between the Clay, geogrid and Stone column and to gain strength of disturbed Clay.

Testing of Clay bed/Stone columns
After construction of plain Clay bed and Stone column, load was applied through the 12mm thick Perspex circular footing having diameter double the diameter of the Stone column (10cm) which represents 25% area replacement ratio. Models were subjected to strain-controlled compression loading in a conventional loading frame at a fast rate of settlement of 0.24mm/min to ensure undrained condition up to a maximum footing settlement of 20 mm. The applied load on footing was observed by a proving ring at every 1 mm settlement. A complete test set up arrangement is shown in Figure 9.
Post test Analysis:
After completion of the test, stone aggregate chips from the column were carefully picked out and a thin paste of Plaster of Paris was poured into the hole and kept it for 24 hours to get the deformed shape of the column. The soil outside the Stone column was carefully removed and the hardened Plaster of Paris is taken out and the deformation properties are studied.

IV. RESULTS AND DISCUSSION

The following are the results obtained by performing the different lab tests.

Soft Clay:
Index and engineering properties of soft Clay are listed in the tables given below.

**Presentation of test results:**
The results for the basic tests conducted on the soft Clay and stone aggregates are given below.

**Test results for Atterberg’s limits:**

![Liquid limit curve for soft Clay](image)

From graph liquid limit =64.3
Plastic limit = 21.7 and Plasticity index = 42.6
Compaction test results

![Compaction Curve for Soft Clay](image1)

**Fig. 11 Compaction curve for soft Clay**

**Load settlement response of plain Clay bed:**
Figure shows the load versus settlement curve obtained from load tests on plain Clay bed. The ultimate load carrying capacity can be obtained by drawing double tangent to the load settlement curve which is shown in figure 12. The ultimate load carrying capacity of the unreinforced Clay bed is 29 kg. The settlement at the ultimate load is 8.1 mm.

![Load-Settlement Curve of Unreinforced Clay Bed](image2)

**Fig. 12 Load-settlement curve of unreinforced Clay bed**

**Load settlement response of ordinary Stone column:**
Figure 13 shows the load-settlement curve obtained from load tests on Clay bed reinforced with Stone column. The load carrying capacity was increased in Clay bed with Stone column when compared to that of plain Clay bed. This is due to densification of the Clay bed by stone aggregate. The ultimate load carrying capacity for Clay bed without Stone
column is 29kg and with Stone column alone is 38 kg. This shows an increment of 31% to that of Clay bed alone. The ultimate load carrying capacity of ordinary Stone column is 38 kg at 7mm settlement.

![Load-settlement curve of ordinary floating Stone column](image1)

**Fig 13. Load-settlement curve of ordinary floating Stone column**

**Load settlement variation of encased Stone column of varying lengths(L length of the Stone column):**
In the further study the Stone column is encased with geo-grids of varying depths from the bottom of the Stone column to have lateral confinement. The load settlement variation can be obtained by variation of reinforcement depths(0.25L, 0.5L, 0.75L and L from bottom).

**Load settlement response of reinforced Stone column with reinforcement depth of 0.25L.**
The load carrying capacity of reinforced Stone column increased when compared to plain Clay bed and ordinary floating column. The ultimate load carrying capacity of reinforced Stone column with reinforcement depth of 0.25L is 48kg. The settlement at the ultimate load is 6mm. This shows an increment of 15% to that of ordinary floating Stone column. Figure 14 shows the load settlement curve of reinforced Stone column with reinforcement depth 0.25L.

![Load settlement curve of reinforced Stone column with reinforcement depth of 0.25L](image2)

**Fig 14. Load settlement curve of reinforced Stone column with reinforcement depth of 0.25L**
Load settlement variation of reinforced Stone column with reinforcement depth of 0.5L depth:
The ultimate load carrying capacity of reinforced Stone column with geo grid depth of 0.5L is 56kg. This shows an increment of 47% to that of ordinary floating Stone column and an increment of 12.5% to that of encased Stone column of depth 0.25L. The settlement at the ultimate load is 5.5mm. Figure 15 shows the load settlement curve of reinforced Stone column with reinforcement depth 0.5.

![Load settlement curve of reinforced Stone column with reinforcement depth of 0.5L](image1)

Fig. 15 Load settlement curve of reinforced Stone column with reinforcement depth of 0.5L

Load settlement response of reinforced Stone column with reinforcement depth of 0.75L.
The ultimate load carrying capacity of reinforced Stone column with reinforcement depth 0.75L is 68kg. This shows an load increment of 78% to that of ordinary floating column. The settlement at the ultimate load is 5mm. Figure 16 shows the load settlement curve of reinforced Stone column with reinforcement depth of 0.75L.

![Load settlement curve of reinforced Stone column with reinforcement depth of 0.75L](image2)

Fig. 16 Load settlement curve of reinforced Stone column with reinforcement depth of 0.75L
Load settlement response of reinforced Stone column with reinforcement depth of L:
The ultimate load carrying capacity of reinforced Stone column with embedment depth L is 76kg. This shows the increment of 100% to that of ordinary floating column. The settlement at the ultimate load is 4mm. Figure 17 shows the load settlement curve of reinforced Stone column with reinforcement depth of L.

![Load settlement curve of reinforced Stone column with reinforcement depth of L](image)

Comparison of load-settlement responses of reinforced Stone columns with varying reinforcement depths:
The ultimate bearing capacity of reinforced Stone column with reinforcement depths of 0.25L, 0.5L, 0.75L and L are 48kg, 56kg, 68kg and 76kg respectively and the corresponding settlements are 6mm, 5.5mm, 5mm and 4mm. There is an increment of 15%, 47%, 78%, 100% load carrying capacity when compared to ordinary floating Stone column. The increase in load carrying capacity is 1.6, 1.9, 2.3, 2.6 times the load carrying capacity of plain Clay beds alone.
Bulging of Ordinary Stone column:

Figure shows the bulging behavior of Stone column without reinforcement. The detailed values of the horizontal deformations can be obtained at the outer face of the column at an interval of 2.5cm, a graph is plotted between the depths of columns verses horizontal deformation of the Stone column. In case of Clay with Stone column alone at depths (0.25L, 0.5L, 0.75L, L) is shown in figure 19. The maximum bulging is 12mm at 100mm.

Table 5 shows the ultimate load and settlement values at different test conditions

Fig. 18 Load Settlement curves of reinforced Stone columns with varying reinforcement depths.

Ultimate load and settlement response at different reinforcement depths
Bulging of Stone column with reinforcement depth of 0.25L from bottom: Figure 20 shows the horizontal deformation of encased Stone column of depth of 0.25L from the bottom of the Stone column. Due to lateral confinement of Stone column of depth 50mm from the bottom, the bulging declined to 8mm when compared to unreinforced Stone column.

Bulging of Stone column with reinforcement depth of 0.5L from bottom: Figure 21 shows the bulging behavior of reinforced Stone column of depth 0.5L. The ultimate bulging of Stone column is 5mm. Due to lateral confinement of Stone column with geo-grid, the bulging reduced to 5mm when compared to unreinforced Stone column.
Bulging of Stone column with reinforcement depth of 0.75L from bottom
Figure 22 shows the bulging behavior of reinforced Stone column of depth 0.75L. The ultimate bulging of Stone column is 3.5mm. Due to lateral confinement of Stone column with geo-grid the bulging reduced to 3.5mm when compared to unreinforced Stone column.

Bulging of Stone column with reinforcement depth of L from bottom
Figure 23 shows the bulging behavior of reinforced Stone column of full depth. The ultimate bulging of Stone column is 3mm. Due to lateral confinement of Stone column with geo-grid the bulging reduced to 3mm when compared to unreinforced Stone column. The lateral confinement of Stone column to its full depth have a considerable effect in reduction of bulging.
Bulging effect of reinforced Stone column with varying depths of reinforcements

Figure 23 shows the bulging behavior of encased Stone columns with varying depths 0.25L, 0.5L, 0.75L, L. The ultimate settlements are 8mm, 5mm, 3.5mm, 3mm of corresponding depths of reinforcements 0.25L, 0.5L, 0.75L, L, respectively.

Figure 24 shows the bulging behavior of ordinary Stone column, reinforced Stone column of depth 0.25L, reinforced Stone column of depth 0.5L, reinforced Stone column of depth 0.75L, and reinforced Stone column of depth L.
V. CONCLUSIONS

1. Installation of ordinary floating Stone column increased the load carrying capacity of plain Clay bed by 31%.
2. The encasement of Stone column with geogrid increases the load carrying capacity and stiffness of the floating Stone column.
3. The variation in depths of reinforcement influences the load carrying capacity of Stone column. The performance of Stone column is increased to its full reinforcement depth by 58% to that of bottom quarter reinforcement and increased by 100% to that of ordinary floating Stone column.
4. Reinforcement of Stone column with geogrids results in decrease of settlements. There is a decrement of settlement for reinforced Stone column to its full depth by 75% respectively when compared to the ordinary floating Stone column.
5. Bulging of ordinary Stone column decreased by 50% when it is reinforced with geo grid to its full depth.
6. Reinforcement of Stone column to its full depth increases the bearing capacity, reduces settlement and bulging in soft clayey soils.
