ABSTRACT: The “Domain Specific web crawler” is a system or a program which we will design to search information from web. A crawler is an automation tool that traverses the web page for the purpose of extracting information. In domain specific Web crawler, the crawler crawls the pages, which are relevant to our domain. To find the domain related web page we need to visit a Web page and calculate the relevance value. Based on relevance value the selection of page is decided. For a crawler it is not an easy task to download the domain specific Web pages. It focus will be to identify Web pages for a particular domain in web. The usage of internet is immense on a large scale for the past many years. In this survey we are going to discuss about types of crawler, crawling algorithm, relevancy check and machine learning.

KEYWORD: Crawler, Ant, Spider, bot, agent, Automation, Search Engine, Focused, web mining, text analysis

I. INTRODUCTION

A web crawler or spider is a computer program that browses the WWW in sequencing and automated manner. A crawler which is sometimes referred to spider, bot or agent is software whose purpose it is performed web crawling[5]. Today the size of the web is thousands of millions of web pages that is too high and the growth rate of web pages are also too high i.e. increasing exponentially due to this the main problem for search engine is deal this amount of the size of the web. The World Wide net (WWW) having billion websites and looking documents that is additional specific with the user’s needs is progressively tough[3]. As more information becomes available on the Web, finding relevant information from it becomes more difficult too[23].

A web search engine is a software system that is designed to search for information on the World Wide Web. The search results are generally presented in a line of results often referred to as search engine results pages. The information may be a specialist in web pages, images, information and other types of files. Some search engines also mine data available in databases or open directories. Unlike web directories, which are maintained only by human editors, search engines also maintain real-time information by running an algorithm on a web crawler. A web crawler (also known as a robot or a spider) is a system, a program that traverses the web for the purpose of bulk downloading of web pages in an automated manner[9].

A web crawler is a program that, given one or more seed URLs, downloads the web pages associated with these URLs, extracts any hyperlinks contained in them, and recursively continues to download the web pages identified by these hyperlinks. Web crawlers are an important component of web search engines, where they are used to collect the corpus of web pages indexed by the search engine. The types of crawler includes horizontal (BFS), vertical (DFS), periodic, parallel, topical, domain specific, social network, semantic, and dynamic. Challenges of web crawler are web coverage, dynamic web, hidden web, deep web and freshness[9].
The basic architecture of web crawler is given below (Figure1). More than 13% of the traffic to a web site is generated by web search [8]. Today the size of the web is thousands of millions of web pages that is too high and the growth rate of web pages are also too high i.e. increasing exponentially due to this the main problem for search engine is deal this amount of the size of the web. Due to this large size of web induces low coverage and search engine indexing not cover one third of the publicly available web. By analyzing various log files of different web site they found that maximum web request is generated by web crawler and it is on an average 50%.

II. RELATED WORK

Most related work in this area is associated with popular search engines and their crawling algorithms and detailed architecture is kept as a business secret. However, web crawlers such as RBSE, the WebCrawler, the World Wide Web Worm, the crawler of the Internet Archive, an early version of the Google crawler, Mercator, Salticus, the WebFountain and the WIRE have published descriptions of their architecture. Besides structural issues, research about Web crawling has focused on parallelism, discovery and control of crawlers for Website administrators, accessing content behind forms (the “hidden” web), detecting mirrors, keeping the freshness of the search engine copy high, long-term scheduling , and focused crawling. In addition, there have been studies on characteristics of the Web, that affect directly the performance of a Web crawler such as detecting communities, characterizing server response time, studying the distribution of web page changes and proposing protocols for web servers to cooperate with crawlers.
but when we consider changing by one third or more than the changing rate is about 7% weekly.

**MAIN TYPES OF CRAWLER**

1. **Focused Web Crawler**
   Focused Crawler is the Web crawler that tries to download pages that are related to each other. It collects documents which are specific and relevant to the given topic. It is also known as a Topic Crawler because of its way of working. The focused crawler determines the following – Relevancy, Way forward. It determines how far the given page is relevant to the particular topic and how to proceed forward. The benefits of focused web crawler is that it is economically feasible in terms of hardware and network resources, it can reduce the amount of network traffic and downloads. The search exposure of focused web crawler is also huge.

2. **Incremental Crawler**
   A traditional crawler, in order to refresh its collection, periodically replaces the old documents with the newly downloaded documents. On the contrary, an incremental crawler incrementally refreshes the existing collection of pages by visiting them frequently; based upon the estimate as to how often pages change. It also exchanges less important pages by new and more important pages. It resolves the problem of the freshness of the pages. The benefit of incremental crawler is that only the valuable data is provided to the user, thus network bandwidth is saved and data enrichment is achieved.

3. **Distributed Crawler**
   Distributed web crawling is a distributed computing technique. Many crawlers are working to distribute in the process of web crawling, in order to have the most coverage of the web. A central server manages the communication and synchronization of the nodes, as it is geographically distributed. It basically uses Page rank algorithm for its increased efficiency and quality search. The benefit of distributed web crawler is that it is robust against system crashes and other events, and can be adapted to various crawling applications.

4. **Parallel Crawler**
   Multiple crawlers are often run in parallel, which are referred as Parallel crawlers. A parallel crawler consists of multiple crawling Processes called as C-procs which can run on network of workstations. The Parallel crawlers depend on Page freshness and Page Selection. A Parallel crawler can be on local network or be distributed at geographically distant locations. Parallelization of crawling system is very vital from the point of view of downloading documents in a reasonable amount of time.

CROSSMARC, Site navigation, Page-filtering, Link-scoring.  
Present the extraction results according to the user’s personal references and constraints.

IV. CONCLUSION AND FUTURE WORK

A focused crawler is the web crawler that tries to download the pages that are related to each other. The relevancy in data decides the performance of crawler. Many researchers implemented different crawlers using different algorithm and methods to improve the QoS. In this paper the technique which are useful to speedup and give the relevant result are considered. The given table contains different techniques, methods and their achievement. The QoS is achieved by proper threading and rapid text mining. We came to know the advantages and limitation of different algorithm of web crawling. It is possible to create a Hybrid Crawler which will overcome the limitation of algorithm to improve the quality of crawler.
