**ABSTRACT:** This paper deals with the theory and simulation of a closed loop vector controlled induction motor drive system using predictive current controller theory and space vector PWM. For improving the overall performance of the drive system the vector controlled strategy is adopted so as to decouple the stator current components for producing rotor flux and shaft torque. The various analytical equations governing the motor and the associated control and calculation blocks are derived in a connected manner and implemented using SIMULINK. Typical problems encountered in a high-performance drive are formulated and a set of performance characteristics of the system are obtained by repeated runs of the schematic model. These results indicate effective interaction between the power and control circuits leading to highly desirable features like variable frequency, variable voltage operation and field-orientation with independent control of air gap flux and torque of the motor.

**KEYWORDS**: Induction motor drive, predictive current controller, field oriented control, space vector PWM.

#### I. INTRODUCTION

Extensive research on the development of variable speed drives (VSD) using the industry-standard 3-phase cage induction motor have been reported during the last 3 decades. This important area has passed through significant milestones characterised by the following schemes: Fixed frequency variable voltage control suitable for fan or blower type loads; Constant V/F (scalar) control and the Field oriented (vector) control for variety of applications. The advent of Field Oriented control (FOC) invented by Blaschke [1] is a major breakthrough in the area variable speed control of induction motors. It is based upon decoupling of the two components of the stator current, one producing airgap flux and the other producing electromagnetic torque. The scheme requires a 3-phase supply from a PWM inverter, where the voltage, frequency and individual phase angle of the outputs can be controlled. It provides independent control of torque and flux during both dynamic and steady state conditions. One important feature of the field orientation is the knowledge of field angle [2] Krishnan, which is either measured or estimated. Accordingly, FOC is classified into two types: Direct Field Oriented control (DFOC) and Indirect Field Oriented control (IFOC). In view of the cost and accuracy considerations in the measurement of field angle, IFOC has emerged as a very popular scheme for most industrial applications. Here, the rotor flux vector estimation and space orientation are carried out using the machine model and its parameters and the field angle is calculated by feed forward of the slip variable. Similarly, several studies and research have been done to find an appropriate technique for the predictive stator current control of induction motor drives.

In this paper, the full theoretical equations covering the IM model in  $\alpha$ - $\beta$  and d-q frame of references, IFOC block, PCC module and SVPWM inverter are developed and presented in a connected manner. These equations represent the various electro-magnetic and electro-mechanical phenomena present in the system and the conditions to be satisfied for maintaining FOC. There is a deviation in this paper from the two publications [3] and [4] in the PCC block, where the calculations of the required space voltage vector at each sampling instant is obtained more rapidly for increasing the bandwidth of stator current control algorithm. A block diagram covering the various power, control and calculation modules in the form of a feedback system is shown in Fig.1.

Fig.1.IM VSD with IFOC and PCC.

The full SIMULINK schematic containing a number of subsystems along with various parameters and operational data is created for simulating typical problems in a cage induction motor drive system. These are the classical start up transient run under load; Stable run at multiple speed-torque combinations. The performance of the controller and the overall system are investigated by repeated runs of the schematic and a set of simulation results are presented.

#### **II. INDUCTION MOTOR MODEL**

The model of a 3-phase VSI fed cage induction motor covering voltage, current, flux, speed and torque variables in (d-q) axis frame is well-known and is widely used in the literature [2] [5] [6] This model is characterised by sinusoidal flux density distribution in the airgap and no saturation of the magnetic field. This model is well suited for solving various problems related to variable frequency, voltage or current and also speed and torque disturbances etc., during the operation of the machine. The motor can be modelled either in stationary, rotor or synchronously rotating reference frames [2], [5] and the former is used in this paper.

Fig.2 and 3 shows the equivalent d and q axis circuit diagram of the motor in stationary reference frame from which the stator and rotor voltage and flux linkage equations are obtained. [5]

Fig. 3. Equivalent circuit in q-axis of IM

The stator and rotor voltage equations in d-q axes are:

 $v_{qs} = r_s i_{qs} + \frac{d\lambda_{qs}}{dt}$ (1)  $v_{ds} = r_s i_{ds} + \frac{d\lambda_{ds}}{dt}$ (2)

 $0 = r_r i_{qr} - \omega_r \lambda_{dr} + \frac{d\lambda_{qr}}{dt}$  $0 = r_r i_{dr} + \omega_r \lambda_{qr} + \frac{d\lambda_{dr}}{dt}$ (3)(4)

Where  $v_{dr} = v_{ar} = 0$  as the rotor is short circuited and  $\lambda_{dr}$ ,  $\lambda_{qr}$ ,  $\lambda_{ds}$ ,  $\lambda_{qr}$  are the rotor and stator flux linkages in d and q axis respectively As indicated in Fig. 2 and 3 the stator and rotor flux linkage equations are [2]

 $\lambda_{qs} = l_s i_{qs} + l_m i_{qr}$ (5) $\lambda_{ds} = l_s i_{ds} + l_m i_{dr}$ (6) $\lambda_{qr} = l_r i_{qr} + l_m i_{qs}$ (7)(8)  $\lambda_{dr} = l_r i_{dr} + l_m i_{ds}$ where  $l_s = l_{ls} + l_m$  is the stator inductance and  $l_{r=}l_{lr} + l_m$  is the rotor inductance The electromagnetic torque developed is given by [2] [5] The end of the methanical angular velocity  $T_e = \frac{3P}{22} (i_{qs} \lambda_{ds} - i_{ds} \lambda_{qs})$  (9) The torque balance equation while driving a load of torque  $T_L$  is given by  $T_e = T_L + J \frac{d\omega_m}{dt} + B\omega_m$  (10) where  $\omega_L$  is the mechanical angular velocity. The refer angular ve where  $\omega_m$  is the mechanical angular velocity. The rotor angular velocity in electrical radians per second  $\omega_r$  is obtained as

Substituting (11) in (10) we get (11) $T_e = T_L + \frac{2}{p} \int \frac{d\omega_r}{dt} + \frac{2}{p} B \omega_r$ (12) where  $P_r J$  and B represent the number of poles, moment of inertia and viscous friction of the drive system respectively.

#### **III. FIELD ORIENTED CONTROL**

FOC is analogous to the energy conversion process in a DC machine, where field flux is always in quadrature with armature flux, enabiling independent variation flux and torque.[5] .In this paper, Indirect method of FOC is used along with the observer discussed above. Further, to generate a reference torque signal  $T_e^*$ , a speed controller is introduced where the actual speed from the induction motor is compared with the desired speed reference setting to generate the speed error signal and processed through a PI controller. The following set of equations cover the mechanism of generating the above  $T_e^*$ , satisfying the principles of field orientation. The rotor circuit equations can be written as

Solving  $i_{dr}$  and  $i_{ar}$  from eqns. (5)-(8),

$$i_{dr}^{*} = \frac{1}{L_r} \lambda_{dr} - \frac{L_m}{L_r} i_{ds}$$
(13)  
$$i_{qr}^{*} = \frac{1}{L_r} \lambda_{qr} - \frac{L_m}{L_r} i_{qs}$$
(14)

Substituting eqns. (13) and (14) in (3) and (4), we get

$$\frac{d\lambda_{dr}}{dt} + \frac{r_r}{L_r}\lambda_{dr} - \frac{L_m}{L_r}r_r \dot{i}_{ds} - (\omega_s - \omega_r)\lambda_{qr} = 0$$
(15)  
$$\frac{d\lambda_{qr}}{dt} + \frac{r_r}{L_r}\lambda_{qr} - \frac{L_m}{L_r}r_r \dot{i}_{qs} + (\omega_s - \omega_r)\lambda_{dr} = 0$$
(16)

For decupled control, the necessary conditions are [6]

$$\lambda_{qr} = 0, \frac{d\lambda_{qr}}{dt} = 0 \text{ and } \lambda_r = \lambda_{dr}$$
 (17)

Hence the governing equation for slip speed under FOC is obtained as [6]  $\omega_{sl} = \frac{L_m r_r}{L_r \lambda_r} \, i_{qs}$ (18)

which is used for estimating the shaft speed. By transforming the above stator current variables into  $\alpha\beta$  frame, the reference data for the PCC is obtained and used below.

#### **IV. PREDICTIVE CURRENT CONTROL**

#### Dept. of EEE, College of Engineering, Trikaripur (CAPE, Government of Kerala), Cheemeni, Kasaragod, Kerala-671313, India

In this paper, PCC is implemented by computing the voltage required to reach the desired current at the end of next sampling period. The idea is to calculate the desired voltage space vector at the current sampling instant k for realising the transformed desired value of the stator current components  $i_{sd}^*$  and  $i_{sq}^*$  as indicated below

 $\frac{i_{s}(k+1)-i_{s}(k)}{T_{smp}} = \frac{u_{s}^{com}(k)-e(k)}{\sigma l_{s}}$ (19) Hence  $u_{s}^{com}(k) = \left[\frac{i_{s}(k+1)-i_{s}(k)}{T_{smp}}\right]\sigma l_{s} + e(k)$ (20)

where k + 1 is the next sampling instant and  $T_{smp}$  is the sampling interval.

Based upon the calculation of voltage space vector covering both magnitude and sector angle the parameters of PWM waveform for a switching frequency  $f_s$  are determined as presented in [7] [8] [9]

#### V. SIMULATION SCHEMATIC

The simulation schematic covers the full power control and feedback circuits in the form of an overall block diagram is given in Fig. 4

It contains the following subsystems

- i) Induction motor model
- ii) Field oriented control model
- iii) Predictive Current Controller block
- iv) Space Vector PWM module

The details of the above subsystem blocks are presented separately as Figs. 5, 6 and7

Fig. 4 Overall Simulink Schematic with Subsystems

Fig. 7 Simulink Schematic of Predictive Current Control

These subsystems, where the individual input and output variables are indicated, implement the corresponding equations presented in the previous sections and together make up the full schematic.

#### VI. SIMULATION RESULTS

The simulation results are grouped into 2 typical problems as follows:

A) Start up transient under load with specified speed setting and load torque = 10 N-m.

A.1: Variation of speed when the given reference speed = 1500rpm

A.2: Variation of speed when the given reference speed = 1000 rpm

A.3: Variation of speed when the given reference speed = 600rpm

B) Stable run at multiple speed-torque combinations.

B.1: Variation of speed and electromagnetic torque when the load torque = 2Nm and reference speed = 600rpm.

B.2: Variation of speed and electromagnetic torque when the load torque = 2Nm and reference speed = 1500rpm.

B.3: Variation of speed and electromagnetic torque when the load torque = 18Nm and reference speed = 600rpm.

B.4: Variation of speed and electromagnetic torque when the load torque = 18Nm and reference speed = 1500rpm.

Fig.8, 9 and 10 gives the results of the problem (A) for the speed settings of 1500 rpm,1000 rpm and 600 rpm covering a speed ratio of 2.5 : 1

Fig. 8 Variation of speed, reference speed=1500 rpm.

#### VIII. CONCLUSION

By Integrating multiple functional blocks in the form of subsystems, an elaborate SIMULINK schematic of a vector controlled induction motor drive system that is capable of simulating typical problems connected with a high performance digital controlled drive has been developed. The simulation results validate the assumptions and equations used for modelling the related electromagnetic and electromechanical phenomena and the control algorithm and also reveal the significant features of the closed loop drive system. The attainment and retention of field orientation and realization of independent control of airgap flux and shaft torque through predictive control of the stator currents are important results of the investigation. It is found that the drive system is capable of quickly responding to required changes in speed and torque on the load side, and the controller is versatile for fast variation of inverter frequency and voltage.

#### MACHINE AND CONTROL PARAMETERS:

The motor is rated at 5.5KW, 220V, 50Hz and 1440rpm. The motor parameters are  $r_s = 0.183\Omega$ ,  $r_r = 0.277\Omega$ ,  $l_s = 0.0553H$ ,  $l_r = 0.056H$ 

 $l_{\rm m} = 0.0538$ H, P = 4, J = 0.0165Kg-m,

B = 0.000086 N-m/rad/sec.

 $K_{ob} = 0.25$ ,  $K_p = 0.25$ ,  $K_i = 0.025$
